Preface

This is an atlas of finder charts for the Messier, Caldwell, and Astronomical League Urban Observing Program objects.

The charts have a field of 4 degrees at a scale of 13 mm per degree, show stars to magnitude 9.5, and represent of deep-sky objects following the current convention. Circles show fields with diameters of 1, 2, 3, and 4 degrees.

There are versions of the atlas with inverted-image and correct-image charts. This version has correct-image charts, with north up and east to the left, corresponding to the view through a refractor or Cassegrain telescope either without a diagonal or with a correct-image diagonal.

These charts have one obvious flaw: all objects are drawn as either ellipses (galaxies and star clouds) or circles (everything else). This means, for example, that they do not correctly show the contours of M42 and M43.

I created this atlas to assist me as I observed under the light-polluted skies of Mexico City with a 70 mm f/6 refractor. I don't use a conventional finder with this telescope; instead, I star-hop using a 32 mm eyepiece with a true field of about 4 degrees. Under my usual observing conditions, very few objects are immediately obvious, and the charts tell me when I've successfully reached the desired field and where to focus my efforts.

Of course, the obvious question is, but why not just use an all-sky atlas? I do indeed use the *Pocket Sky Atlas* for star-hopping, but for confirming a field no all-sky atlas combines adequate depth with convenience at the telescope, and none really give me the sense of what I see through the eyepiece.

To some degree, the relation between these charts and the *Pocket Sky Atlas* is similar to the relation between the large-scale and small-scale charts in *The Observer's Sky Atlas*. The small-scale all-sky atlas is to find the field and the large-scale charts are to confirm the field and locate the object. (I don't use *The Observer's Sky Atlas* at the telescope, because the small-scale charts are too shallow and too narrow, the large-scale charts aren't inverted, and the binding is inconvenient.)

Chapter 1

The Messier Objects

The Messier objects are probably the most famous deep-sky objects. I find O'Meara's *Deep-Sky Companion: The Messier Objects* to be excellent on the origin of the catalog, the appearance of the objects, and their nature.

The following table lists the objects with their J2000 positions (decimal hours of right ascension and degrees of declination), the charts on which they appear in the *Pocket Sky Atlas*, their types, and other names. I follow O'Meara in identifying M102 as NGC 5866.

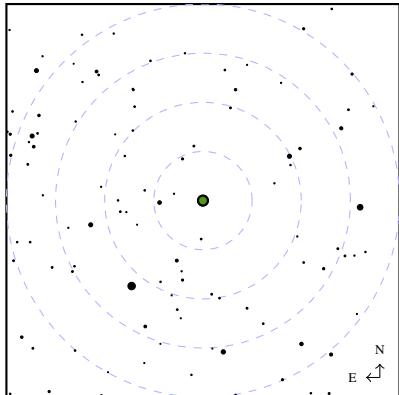

For completeness, I include finder charts for all of the Messier objects, even bright ones like M45.

| Name | Position | PSA | Type | Other Names |
|------|----------|-------|------|-------------------------------------|

Chapter 2

The Caldwell Objects

The Caldwell objects were selected by Patrick Moore as a complement to the Messier objects. Again, I find O'Meara's *Deep-Sky Companion: The Caldwell Objects* to be excellent on the origin of the catalog, the appearance of the objects, and their nature.

I use C1 to C109 to label the Caldwell objects. This is common practice, but does not confirm to the IAU's recommendation on nomenclature, as O'Meara rightly notes (pp. 14–15).

The following table lists the objects with their J2000 positions (decimal hours of right ascension and degrees of declination), the charts on which they appear in the *Pocket Sky Atlas*, their types, and other names. I follow the corrections given by O'Meara (p. 15) with regards to C37, C49, C89, and C100.

For completeness, I include finder charts for all of the Caldwell objects, even bright ones like C41 (the Hyades).

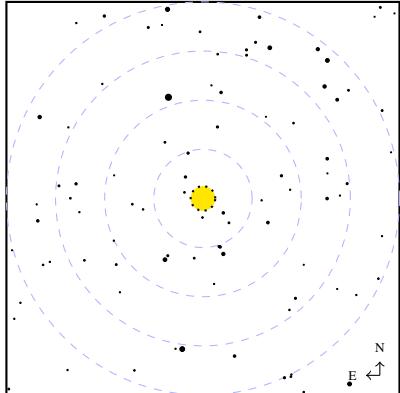

I note that C41 (the Hyades) and C99 (the Coalsack Nebula) are much bigger than the finder charts. They are really binocular objects and are better located using a small-scale all-sky atlas.

Chapter 3

The Urban Observing Program Objects

The Astronomical League Urban Observing Program consists of bright objects selected by Terry Trees for northern observers under light-polluted skies. There are 87 deep-sky objects, 12 double stars, and 1 variable star. The deep-sky objects range in declination from -35 to $+72$ degrees, cover all seasons, and include 41 Messier objects and 14 Caldwell objects.

I give finder charts for the deep-sky objects only; the stars are all no fainter than magnitude 5.2 and have Bayer designations, and so a standard all-sky atlas is adequate. I use U1 to U87 to label the deep-sky objects, following the order in right ascension given by Trees, but this is not a standard designation. For completeness, I include all of the deep-sky objects, even bright ones like the Hyades (U18).

The following table lists the deep-sky objects with their J2000 positions (decimal hours of right ascension and degrees of declination), the charts on which they appear in the *Pocket Sky Atlas*, their types, and other names.

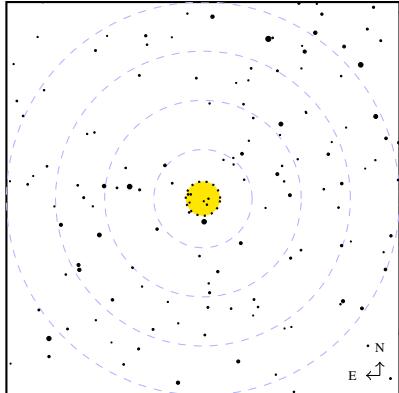

I note that the Hyades (U18) and Coma Star Cluster (U44) are much bigger than the finder charts. They are really binocular objects and better located using a small-scale all-sky atlas. That said, be aware that the α Per Cluster (U15) and Coma Star Cluster (U44) are not labelled in the *Pocket Sky Atlas*.

For information on the 55 Messier and Caldwell objects, I would refer you to O'Meara's *Deep-Sky Companions* books. His *Messier Objects* volume also covers U72 (p. 395) and his *Caldwell Objects* volume also covers U19 (p. 509) and U87 (p. 503). For the remaining objects, you might start at Wikipedia.
